

Why the current site is not fit to sell from

A store with 44 products should be light, quick on a phone, and impossible to distrust. On the measurements taken on 24 August 2026, letsfoodify.com is none of the three — and the reasons are structural, not cosmetic.

Prepared by Mindlayer for Nalin Agarwal Evidence: site audit of 24 Aug 2026 Issued 16 Sep 2026

The short version

The site is built on six page-builder plugins that between them load 133 script and style files on every page, ask 25 questions at checkout, tell the customer nothing about search engines, and carry text that is invented. Each of those is a fixable symptom. Together they say the platform underneath cannot be tuned into a good store — the front end has to be rebuilt on the same WooCommerce back office the business already runs on, with the product URLs preserved so nothing already ranking is lost.

What was measured

These are the figures the case rests on. Every one was taken by hand from the live site on 24 August 2026; the target beside each is the budget the rebuild is held to by an automated gate that refuses to deploy if it is missed.

179 requests to load the homepage target ≤ 55	2.5 _{MB} homepage weight, before any product image is tapped target ≤ 900 KB	73 _{+ 60} separate JavaScript and CSS files per page target $12 + 6$	140 products rendered on the homepage — for a 44-product catalogue target 8
25 fields to fill in at checkout target 9	0 product pages with a meta description target 44 of 44	437 pieces of text set at 11.6 px floor 16 px	308 tap targets smaller than 44 px floor 44 px

Page and request figures are for the homepage on a cold load. Type and tap-target counts are across the audited templates. Core Web Vitals field data (what Google actually scores) was not available — see the evidence limits at the end.

Five reasons, in the order they cost money

1. The checkout loses the sale at the last screen **HIGHEST COST**

MEASURED

Twenty-five fields for a first order. A price that changes at the final step — ₹210 in the cart becoming ₹285 once shipping and handling appear. No cash on delivery. The checkout is the same page chrome as the rest of the site, switched between boxes by injected JavaScript, and the script's own developer note is visible on the login page as body text:

```
// 3. Inject JS step-switching script to show only one box at a time
```

WHAT IT COSTS

Every field is a place to give up, and a price that grows at the end is the single most reliable way to abandon a cart in Indian D2C. A visible code comment on the sign-in page tells a careful buyer the site is not looked after.

REBUILD

Nine fields, email required, state as a list, PIN code filling city and state. The cart shows the shipping it will actually charge and promises nothing else is added. Cash on delivery with a named prepaid saving. A stripped checkout page with no navigation to leave by. Returning customers type no address at all.

2. Trust signals on the site are fabricated **REPUTATIONAL**

MEASURED	Every product page says "70 people are viewing this right now". The homepage carries three testimonials, all attributed to the same name, SUJATA. Product reviews are switched off, so no real customer can leave one. The shipping line in the cart reads . : ₹55 . 00 because a shipping method is titled with a full stop. The footer says © 2025.
WHAT IT COSTS	A buyer who notices one invented number distrusts every other number on the page, including the price. Fake urgency counters are also the kind of pattern Google issues manual actions for. And these are the details a first-time visitor to an unknown food brand is looking for.
REBUILD	No social proof the site cannot prove. Reviews on, with a verified-purchase label and a review request sent only after delivery — never after a refund. Google Business Profile reviews pulled live with real names and real counts. Stock shown only when it is genuinely low. The year is computed.

3. It is slow because of what it is built from **STRUCTURAL**

MEASURED	179 requests and 2.5 MB for the homepage; 73 JavaScript and 60 CSS files, produced by Elessi and its child theme, Elementor, Elementor Pro, Slider Revolution, Essential Addons and nasa-core loading together on every page. The homepage renders 140 product tiles for a catalogue of 44.
WHAT IT COSTS	On a 4G phone — where most Indian D2C traffic arrives — this is a homepage that takes seconds to become usable. Page speed is also a ranking input. This cannot be fixed by tuning: the weight is the builder stack itself, and each plugin brings its own scripts to every page whether that page uses them or not.
REBUILD	A standalone block theme with no page builder: all six plugins removed, one stylesheet inlined, two self-hosted fonts preloaded, scripts deferred, eight best sellers on the homepage. The budget — 55 requests, 900 KB, 12 scripts, 6 stylesheets — is enforced at deploy time, not hoped for.

4. Search engines are given nothing to work with **COMPOUNDING**

MEASURED	No SEO plugin installed. Zero of 44 product pages carry a meta description; none carry social sharing tags. Around 170 product-tag archives are open to indexing, each a thin page competing with the 44 real ones. The sitemap is WordPress's generic default.
WHAT IT COSTS	With nothing to quote, Google writes its own snippet for every product, and the tag pages spread whatever authority the site has across 200-odd URLs instead of 44. This is a cost that compounds monthly and is invisible until someone looks.
REBUILD	Rank Math with a description on every product, checked across all 44 rather than sampled. Tags become filterable attributes; the archives are de-indexed for 30 days, then redirected — never deleted into a 404. Product and category URLs are frozen byte-for-byte so nothing already ranking moves. A Google Merchant Center feed, generated from the same product fields the pages show.

5. It was designed for a desktop and squeezed onto a phone **USABILITY**

MEASURED	437 elements set at 11.6 px text. 308 links and buttons below the 44 px minimum a thumb needs. Form borders at 1.3:1 contrast against the page, which fails the accessibility floor for a control.
WHAT IT COSTS	Small text is pinched to read and small targets are mis-tapped; on a phone both turn into "I'll do it later". Accessibility failures are also a compliance exposure as the site grows.
REBUILD	Designed at 360 px first. 16 px is the floor for anything a customer reads, 44 px for anything they tap, and every colour pairing is measured against WCAG — by a test that fails the build if a future change breaks one.

What the current site cannot do at all

Beyond the defects, there are things the business has asked for that the present platform has no way to deliver:

- **Partner and creator coupons that report back.** A code that emails the partner the items and value of each order it was used on — never the buyer's details — with a ledger the team can read and export. This is the one genuinely custom build in the project.
- **Mobile-number sign-in with a saved address book,** guest checkout kept as the default. Depends on DLT registration for transactional SMS, which the client owns.
- **Structured pack declarations** — FSSAI licence, net quantity, allergens, veg mark, country of origin, consumer care — as fields on every product page, not free text. The same fields feed the Google product listing, so the compliance work pays twice. An absent declaration is shown as absent, never hidden.
- **GST-correct invoicing** with the intra- and inter-state split driven by the delivery address, and a courier manifest from the same data.
- **An admin screen a non-technical owner can run the day from:** today's orders, revenue, low stock, pending fulfilment — plus a staff role that is not full administrator.

Why not patch it

Some of this is patched already. The leaked comment, the viewer counter, the duplicated testimonials, the shipping label, the footer year and the missing SEO plugin are the week-one emergency fixes, applied to the live site behind their own verification gate.

But the ceiling is the stack. The six builder plugins are the reason for the 133 files, and they are also the reason the checkout is a page of injected scripts and the templates cannot be reasoned about. Removing them is not a patch — it is the rebuild. Doing it on the same WooCommerce back office, with the same products, orders and customers, and with the URLs frozen, is what makes the rebuild safe: the business keeps everything that works and replaces only the layer the customer sees.

Evidence and its limits

Where the numbers come from. Every figure above was measured by hand in a browser on 24 August 2026 and recorded in the project audit. Nothing is estimated from a screenshot.

What has not been re-measured. The build environment cannot reach letsfoodify.com, so these figures have not been re-taken since the audit; the week-one fixes will have changed the trust findings. The hosting cache reading taken that day was polluted by a cart cookie in the same browser and should be re-tested clean before it is used to justify a host move.

What is not known. Core Web Vitals field data — the speed score Google uses — needs Search Console access, which is outstanding. Traffic, conversion rate and orders per month, which would size every figure here in rupees, have not been shared. The audit shows the site is heavy, leaky and untrustworthy; it cannot yet say how many orders that is costing per month.

The rebuild is complete in code and gated by 29 automated test suites, including one that will not let it launch without the correct search-engine settings. What remains is the client-owned input — FSSAI licence number, GST details, product photography and weights, gateway and SMS credentials — and a launch week on real infrastructure.
